

Daily Work Report – ARBE Module

BY: NIVASHINI S R

1. Tasks Completed Today

- I went through the complete requirement document for the Automated Research & Blog Engine (ARBE) and understood how the system is designed to function end-to-end.
- I learned the basic concepts of the stock market such as indices, sectors, stock movements, volume, breakouts, mutual fund trends, and macroeconomic indicators to clearly understand how signal detection works.
- Additionally, I reviewed the workflow (Draft → Review → Approve → Publish) and the types of content ARBE needs to generate, such as Market Summaries, Stock Spotlights, MF Notes, and Macro Updates.

2. Work in Progress

- I am currently working on understanding the different types of signals (market, stock, sector, MF, and macro) and how each signal should trigger a specific content template.
- I am mapping out how the data acquisition and caching layer works, and how the system identifies when an event is “important enough” to generate content.
- Along with this, I am going through the RhoFi website to understand its features, structure, and overall functionality.

3. What I Understood About My Module

The ARBE module is designed to automatically detect key financial events—such as significant market moves, stock price spikes, high-volume activity, sector rotations, mutual fund trends, and macroeconomic news—and convert them into short, enriched, 1–3 minute insights.

Whenever a signal is detected, the engine must:

- Map it to the correct content template
- Generate a draft using AI
- Move the content through a review workflow

- Publish the final article with SEO metadata
- Trigger notifications for users

The module aims to reduce manual writing effort and ensure that RhoFi provides consistent daily market insights. My role is to understand the logic behind signal detection, content generation templates, and the publishing workflow.

4. Questions Raised

1. What are the exact thresholds for each type of signal (market, stock, MF, macro)?
2. At what frequency should the system check for signals (real-time, hourly, daily)?
3. Which parts of the workflow should be automatically triggered vs. manually controlled by the admin?
4. Do we need to log failed signal detections or skipped events for debugging?
5. Should draft content be automatically regenerated if the underlying data updates before publishing?
